#### **Quiz: Linear Regression with multiple variables**

# Question 1: Suppose m=4 students have taken some class, and the class had a midterm exam and a final exam. You have collected a dataset of their scores on the two exams, which is as follows:

midterm exam	(midterm exam) <sup>2</sup>	final exam
89	7921	96
72	5184	74
94	8836	87
69	4761	78

You'd like to use polynomial regression to predict a student's final exam score from their midterm exam score. Concretely, suppose you want to fit a model of the form  $h_{\theta}(x) = \theta_0 + \theta_1 x_1 + \theta_2 x_2, \text{ where } x_1 \text{ is the midterm score and } x_2 \text{ is (midterm score)}^2.$  Further, you plan to use both feature scaling (dividing by the "max-min", or range, of a feature) and mean normalization.

What is the normalized feature  $x_2^{(2)}$ ? (Hint: midterm = 72, final = 74 is training example 2.) Please round off your answer to two decimal places and enter in the text box below.

**Results: Incorrect** 

### **Question 2:**

2. You run gradient descent for 15 iterations

with lpha=0.3 and compute J( heta) after each

iteration. You find that the value of  $J(\theta)$  increases over

time. Based on this, which of the following conclusions seems

most plausible?

Rather than use the current value of  $\alpha$ , it'd be more promising to try a larger value of  $\alpha$  (say  $\alpha=1.0$ ).

lpha=0.3 is an effective choice of learning rate.

Rather than use the current value of  $\alpha$ , it'd be more promising to try a smaller value of  $\alpha$  (say  $\alpha=0.1$ ).

**Results: Correct** 

#### **Question 3:**

← Linear Regression with Multiple Variables

1	3.	Suppose you have $m=28$ training examples with $n=4$ features (excluding the
point		additional all-ones feature for the intercept term, which you should add). The normal
		equation is $ heta = (X^TX)^{-1}X^Ty$ . For the given values of $m$ and $n$ , what are the
		dimensions of $\theta$ , $Y$ , and $\theta$ in this equation?

X	İs	28	X	4	$\eta$	is	28	X	1.	θ	is4	Х	1

$$X$$
 is  $28 \times 5$ ,  $y$  is  $28 \times 5$ ,  $\theta$  is  $5 \times 5$ 

$$X$$
 is  $28 \times 4$ ,  $y$  is  $28 \times 1$ ,  $\theta$  is  $4 \times 4$ 

$$\bigcirc$$
 X is  $28 \times 5$ , y is  $28 \times 1$ ,  $\theta$  is  $5 \times 1$ 

**Results: Correct** 

#### **Question 4**

4. Suppose you have a dataset with m=1000000 examples and n=200000 features for each example. You want to use multivariate linear regression to fit the parameters  $\theta$  to our data. Should you prefer gradient descent or the normal equation?

$\bigcirc$	The normal equation,	since	gradient	descent	might l	be ur	nable t	to f	find	the
	optimal $\theta$ .									

- Gradient descent, since  $(X^TX)^{-1}$  will be very slow to compute in the normal equation.
- Gradient descent, since it will always converge to the optimal heta.
- The normal equation, since it provides an efficient way to directly find the solution.

**Results: Correct** 

## **Question 5**

5.	Which of the following are reasons for using feature scaling?					
		It speeds up solving for $ heta$ using the normal equation.				
		It is necessary to prevent gradient descent from getting stuck in local optima.				
		It prevents the matrix $X^TX$ (used in the normal equation) from being non-invertable (singular/degenerate).				
		It speeds up gradient descent by making it require fewer iterations to get to a good solution.				

**Results: Correct**
